Random noise model

Parametrization

This model simply defines § to be a vector of independent and Gaussian distributed random variable with precision τ:

$$\pi(\mathbf{x}|\tau) \propto \tau^{n/2} \exp\left\{-\frac{\tau}{2}\mathbf{x}^T\mathbf{I}\mathbf{x}\right\}$$

where $\mathbf{I}$ is the identity matrix.

Hyperparameters

The precision parameter τ is represented as

$$\theta = \log \tau$$

and the prior is defined on θ.

Specification

The independent model is specified inside the `f()` function as

```
f(<whatever>,model="iid",prior=c(<prior.model.theta>),
              param=c(<param.prior.theta>))
```

Example

```
n=12
Ntrials = sample(c(80:100), size=n, replace=TRUE)
eta = rnorm(n,0,0.5)
prob = exp(eta)/(1 + exp(eta))
y = rbinom(n, size=Ntrials, prob = prob)

data=data.frame(y=y,z=1:n)

formula=y~f(z,model="iid",prior="loggamma",param=c(1,0.01))
result=inla(formula,data=data,family="binomial",Ntrials=Ntrials)
```
