# Besag2 model for weighted spatial effects

#### Parametrization

The besag2 model is an extention to the besag model. Let the random vector  $\mathbf{z} = (x_1, \dots, x_n)$  be the besag model, then the besag2 is the following extentions

$$\mathbf{x} = (a\mathbf{z}, \mathbf{z}/a)$$

where a > 0 is an additional hyperparameter and  $\dim(\mathbf{x}) = 2n$ , and  $\mathbf{z}$  is the *same* (up to tiny additive noise) random vector.

## Hyperparameters

This model has two hyperparameters  $\theta = (\theta_1, \theta_2)$ .

The precision parameter  $\tau$  is represented as

$$\theta_1 = \log \tau$$

and the prior is defined on  $\theta_1$ .

The weight-parameter a is represented as

$$\theta_2 = \log a$$

and the prior is defined on  $\theta_2$ .

## Specification

The besag2 model is specified inside the f() function as

The precision is the precision defining how equal the two copies of z is. The neighbourhood structure of x is passed to the program through the graph.file argument. The structure of this file is described below.

Note that the besag2 model has dimension 2n, where n is the size of the graph.

The option adjust.for.com.comp adjust the model if the graph has more than one connected component, and this adjustment can be disabled setting this option to FALSE. This means that constr=TRUE is interpreted as a sum-to-zero constraint on *each* connected component and the rankdef parameter is set accordingly.

### Hyperparameter spesification and default values

## hyper

#### theta1

name log precision short.name prec prior loggamma param 1 5e-05 initial 4 fixed FALSE

```

set.default.values TRUE
pdf besag2
```

### Structure of the graph file

We describe the required format for the graph file using a small example. Let the file gra.dat, relative to a small graph of only 5 elements, be

```
5
1 1 2
2 2 1 3
3 3 2 4 5
4 1 3
```

Line 1 declares the total number of nodes in the graph (5), then, in lines 2-6 each node is described. For example, line 4 states that node 3 has 4 neighbours and these are nodes 2, 4 and 5.

The graph file can either have nodes indexed from 1 to n, or from 0 to n-1. Note that in the latter case, node i seen from R corresponds to node i-1 in the 0-indexed graph.

## Example

This is a simulated example.

```
data(Oral)
g = system.file("demodata/germany.graph", package="INLA")
## use data Oral to estimate a spatial field in order to simulate a
## 'realistic' dataset.
```

```
formula = Y ~ f(region, model="bym", graph.file=g)
result = inla(formula, data = Oral, family = "poisson", E = E)
x = result$summary.random$region$mean
n = length(x)/2
\#\# simulate two new datasets. 'a' is the weighting between the
## log.rel.risk:
a = 2
xx = x[1:n]+1
x = c(a*xx, xx/a)
E = c(Oral$E, Oral$E)
N = 2*n
y = rpois(N, lambda = E*exp(x))
## model='besag2' defines a model with length N = 2*graph->n, the
## first half is weighted with 'a' the other half is weighted with
## 1/a. here there is no unstructed terms.
i = 1:N
formula = y ~ f(i, model="besag2", graph.file=g) -1
r = inla(formula, family = "poisson", data = data.frame(E,y,i), E=E, verbose=TRUE)
```

## Notes

The besag2 model has default constr=FALSE, and constr=TRUE does not make sense.
