# Proper/Non-intrinsic Besag model for spatial effects

#### Parametrization

The proper version of the Besag model for random vector  $\mathbf{x} = (x_1, \dots, x_n)$  is defined as

$$x_i|x_{-i}, \tau, d \sim \mathcal{N}\left(\frac{1}{d+n_i} \sum_{i \sim j} x_j, \frac{1}{\tau(d+n_i)}\right)$$
 (1)

where  $n_i$  is the number of neighbours of node i,  $i \sim j$  indicates that the two nodes i and j are neighbours, d > 0 is an extra term added on the diagonal controlling the "properness" and  $\tau > 0$  is a "precision-like" (or scaling) parameter.

This parameterisation corresponds to this precision matrix  $Q = (Q_{ij})$ , where for  $j \neq i$ 

$$Q_{ii} = \tau(n_i + d)$$
 and  $Q_{ij} = -\tau$ .

# Hyperparameters

The precision parameter  $\tau$  is represented as

$$\theta_1 = \log \tau$$

and the prior is defined on  $\theta_1$ . The diagonal parameter d is represented as

$$\theta_2 = \log d$$

and the prior is defined on  $\theta_2$ .

#### Specification

The besag model is specified inside the f() function as

```
f(<whatever>, model="besagproper", graph.file=<graph file name>,
    hyper=<hyper>)
```

The neighbourhood structure of x is passed to the program through the graph.file argument. The structure of this file is described below.

## Hyperparameter spesification and default values

## hyper

```
theta1
```

name log precision short.name prec prior loggamma param 1 5e-04 initial 2 fixed FALSE to.theta from.theta

theta2

name log diagonal

```
short.name diag
         prior loggamma
         param 11
        initial 1
        fixed FALSE
         to.theta
         from.theta
constr FALSE
nrow.ncol FALSE
augmented FALSE
aug.factor 1
aug.constr
n.div.by
n.required TRUE
set.default.values TRUE
pdf besagproper
```

## Structure of the graph file

We describe the required format for the graph file using a small example. Let the file gra.dat, relative to a small graph of only 5 elements, be

Line 1 declares the total number of nodes in the graph (5), then, in lines 2-6 each node is described. For example, line 4 states that node 3 has 4 neighbours and these are nodes 2, 4 and 5.

The graph file can either have nodes indexed from 1 to n, or from 0 to n-1. Note that in the latter case, node i seen from R corresponds to node i-1 in the 0-indexed graph.

## Example

```
## pick a graph
graph.file = system.file("demodata/germany.graph", package="INLA")
g = inla.read.graph(graph.file)

## we will use replicated samples in our testing
nrep = 5

## make life easy; use dense matrix algebra
d = 1.0
tau = 1.0
Q = matrix(0, g$n, g$n)
```

```
diag(Q) = tau * (d + g$nnbs)
for(i in 1:g$n) {
    if (g$nnbs[i] > 0) {
        Q[i, g$nbs[[i]]] = -tau
        Q[g$nbs[[i]], i] = -tau
    }
}
R = chol(Q) ## 'chol' returns the upper triangular
## simulate data with replications
y = c()
for(i in 1:nrep) {
    y = c(y, backsolve(R, rnorm(g$n)))
i = rep(1:g$n, nrep)
replicate = rep(1:nrep, each = g$n)
formula = y ~ f(i, model="besagproper", graph.file = graph.file,
        replicate=replicate,
        hyper = list(diag = list(param = c(1, 1)))) -1
## use 'exact' observations, so we fix the noise precisin to a high
## value
r = inla(formula,
        data = data.frame(y, i, replicate),
        family = "gaussian",
        control.family = list(
                hyper = list(
                        prec = list(
                                initial = 10,
                                fixed=TRUE))))
```

#### Notes

If d=0 and the parameter rankdef=1 is set, then this model corresponds to the besag model. constr=FALSE is default for this model.
